The below theorem is used everywhere.

Theorem 0.1 (Fourier Integral):

$$\int_0^{2\pi} e^{imx} dx = \begin{cases} 2\pi(m=0) \\ 0 \quad (m \in \mathbb{Z} \setminus \{0\}) \end{cases} \quad (1)$$

Proof:

$$\int_0^{2\pi} e^{imx} dx = \frac{e^{im \cdot 2\pi} - e^{im \cdot 0}}{im} \quad (2.1)$$

$$= \begin{cases} 2\pi(m=0) \\ 0 \quad (m \in \mathbb{Z} \setminus \{0\}) \end{cases} \quad (2.2)$$

- Integral equations coming from common partial differential equations in $\mathbb{S}^1$ ($\mathbb{R}^2$) often involve singular integrals, derivative of integrals.
- To compute these integrals, exact values of integrals of Fourier basis functions are needed.
- To deal with the singularity while maintaining 2π -periodicity, we need a function which only has singularity at $0(2\pi)$ and is 2π -periodic.
 - $\csc^n t, \cot^n t, n \in \mathbb{N}$: singularities at π as well
 - $\csc^n \frac{t}{2}, n \notin 2\mathbb{N}$: not 2π -periodic
 - $\cot^n \frac{t}{2}, n \in \mathbb{N}$: ok
 - $\csc^{2n} \frac{t}{2}, n \in 2\mathbb{N}$: ok
